AGROMETEOROLOGICAL BULLETIN

MARCH 1984

The Weather of March

Following some rain on March 1 and showers in a strong northwesterly airflow on 2nd, weather conditions from 3rd to 10th were dominated by high pressure over Ireland. Conditions were generally mild, cloudy and frost-free. With some decline in pressure, a cold frontal passage occurred on 11th and a strong north to northeast airflow set in. There were some showers or spells of rain, which turned to sleet and snow in many places on 13th and 14th, but as pressure rose again the spell from the 15th to 20th was largely dry. While conditions were cloudy, west and northwest areas had good sunny spells and with the clear skies at night frost became sharp in these regions.

Pressure declined about March 20th and frontal rainbelts moved inland from the west of Ireland. An extensive region of low pressure, having a number of depression centres, influenced the area. This development resulted in variable winds over Ireland, which were strong at times. In particular a south to southeast airflow became strong and gusty on 23rd as a deepening wave depression of the system crossed the country. This system later induced a west to northwest airflow in its wake with showers or outbreaks of snow.

Low pressure affected the country until the 28th, during which further troughs passed northwards through the country, preceded by periods of cold southeast to northeast winds and spells of rain, which turned to snow at times. As pressure slowly recovered on 29th, winds gradually veered during the following days from the northwest, through the northeast becoming moderate to fresh easterly on 31st. The period was dry with good sunny spells, except in southern areas.

Monthly Amounts of Precipitation were generally below normal except in parts of the south midlands. Values varied from 45% at Valentia Observatory to 131% at Oak Park, Co. Carlow and at Kilkenny. Wettest day was the 23rd; many areas received between 20 and 30mm precipitation. The wettest spells occurred on 1st/2nd, 11th to 14th, and from 21st to 25th (and up to 27th in some places).

Mean Monthly Air Temperature was below normal everywhere, varying from 0.5°C below at Clones to 1.4°C below at Valentia Observatory. Soil temperatures (100mm) were above average by up to 2.4°C to March 10th; subsequently they fell to about 1.5°C to 2.0°C below average and remained well below average for the rest of the month. Degree days (threshold 4.4°C) were also well below average, mostly in the range 60% to 70% of average. While air frost was not severe the occurrences of ground frost were widespread except in the period 4th to 10th. The most severe ground frost occurred at Claremorris on 19th where a grass minimum of -9.1°C was recorded.

Mean Duration of Bright Sunshine was well below normal almost everywhere and was as little as 54% of normal at Birr. The exception was Belmullet where the duration was 107% of normal. Global radiation was 73% of average at Valentia (sunshine was 83.3% of average for the same period; 1969-82), and 87.5% of average at Dublin Airport (sunshine was 69.9% of average for the period 1976-82).

Strong Winds with Gale Gusts occurred on 1st/2nd, 11th/12th, on 23rd when gales were widespread, and on 31st. Summary Below normal temperature, much below normal sunshine, except in the extreme west, and below normal rainfall except in parts of the midlands.

The data contained in this Bulletin are Provisional. Some of the material in Table 1 will be published in its final form later in the Monthly Weather Report; final values of Solar Radiation at stations in Table 2 will be published in the Annual Summary of Solar Radiation.

special topic

CLIMATE AND HORTICULTURE

P.I. Tiernan

Dept. of Horticulture, University College Dublin.

The good grower knows his climate because growth and development of his crops are dependent to a very large extent on climatic factors. These factors and their effects on plant growth are extremely complex because the plant is never subjected to just a single factor at any given time but to a continuous interaction with innumerable combinations of factors. While the grower may not be able to change the climate he is able to adjust his cropping practices to fit the climate.

At best the application of the grower's knowledge of his climate is limited when that knowledge is based on general climatic patterns. Of much more relevance to his needs is a knowledge of the local climate which represents small scale local departures from the general climatic pattern. Several factors affect this local climate - altitude, aspect, local topography and proximity to the sea to mention but a few.

Height above sea level may have the effect of shortening the growing season by as much as six to ten days per 30m in altitude while temperature may be reduced by 1°C for every 150m rise in altitude. Sunshine is reduced with increase in altitude while rainfall and wind are increased. Regarding aspect the main effect of a south, south-east or south-west facing field is to increase the warmth of the sunshine falling on the soil and on the crops. The growing season on a south facing slope may be 20 days longer than on a north facing one. Favourable aspect tends to create earliness but this advantage may be negated if the slope is exposed to strong winds. The topography or shape of the surrounding land can have a major effect on local weather, an effect which may not be obvious from general climatic data. As already mentioned mean temperatures decrease with height but on cold, cloudless and windless nights the lowest temperatures are found in lowlying areas, not on hillsides. Therefore this factor must be considered when siting any crop which is susceptible to frost. Proximity to the coast produces a rapid change of climate but not all changes are beneficial to crop production. The major advantage of closeness to the sea lies in increased sunshine and decreased risk of frost occurrence. The major disadvantage is the increased liability to strong winds and with them the distinct possibility of damage due to salt sprays.

When we think of climate and horticulture we tend to think primarily of temperature, light and moisture. This is justifiably so as these are the primary requirements for crop growth. Indeed plants may be classified according to their response to any one of these climatic factors. There are many examples of where these factors interact with each other. For instance the influence of daylength on plant development is often modified, and sometimes even inhibited, by other environmental factors, particularly temperature. Many plants do not respond to light duration unless their thermal requirements are met, as is seen in the case of biennial plants which fail to flower until they have passed through a period of low temperature.

Through a better understanding of the effects of climate on crop production the grower becomes more aware of the value of keeping accurate weather records. The result is that the data in this Bulletin become much more meaningful.
