

METEOROLOGICAL SERVICE

AGROMETEOROLOGICAL BULLETIN

JULY 1984

The Weather of July

The high pressure, which was established over Ireland on June 27, giving bright and warm conditions, declined on July 7th. A southerly airflow set in on July 8th. Complex frontal troughs to the west of Ireland began to affect the country on 8th/9th and an unsettled spell of weather ensued. Widespread rain or showers occurred in this spell up to 11th. As a depression centre drifted slowly northwards off the west coast a southwest to west airflow set in and further frontal waves drifted slowly across the country with outbreaks of rain or drizzle on 12th/13th.

A return of high pressure on 14th and 15th brought a renewal of the fine spell, although weak frontal troughs affected some places in the west and north on 16th/17th. This high, which was mainly centred to the northwest of the country, dominated weather conditions until 27th. A light to moderate northeasterly airflow prevailed during the period and thundery troughs affected southern coastal counties on 24th/25th.

As the high cell declined weak frontal troughs affected the northwest and northern regions on 28th. A deepening wave to the west of the country on 29th was followed by a slow passage of a cold front over the country from the west on 30th, and extensive rain occurred on 30th and early on 31st.

Monthly Amounts of Precipitation were well below normal in almost all areas. Amounts varied from 92% of normal at Valentia Observatory to 21% at Johnstown Castle, the majority being in the range 40% to 70%. Amounts at Galway were only 26% of normal, reflecting a particularly dry spell in the Clare/Galway region. Wettest spells of the month occurred from 8th to 14th; local thundery showers occurred in southern regions on 24th/25th, and another wet spell began in western areas on 28th and became widespread on 30th/31st. Soil moisture deficits continued to mount during the month in all areas; while still only some 35mm to 45mm at extreme western stations, midland and southeast stations reached some 80-100mm or more, reflecting the great stress caused to plants due to lack of moisture. Weather favourable to the spread of potato blight was well below average, the more significant spells occurring from 10th to 12th, 14th, 16th to 20th in the extreme northwest, 20th to 22nd in extreme southern areas, and 28th/29th in the northwest.

Mean Monthly Air Temperature was well above average generally, ranging from 1.9C° above average at Shannon Airport to 0.6C° above at Rosslare and Malin Head. Degree days, threshold 10C°, were mostly between 25% and 35% above average. Soil temperatures (100mm) varied from 2.8C° above average at Shannon Airport to 0.9C° above at Clones. Sharp ground frost occurred in the midlands and parts of the south on 3rd and again in the midlands on 16th and 22nd.

Mean Duration of Bright Sunshine was well above normal, varying from 153% of normal at Dublin Airport to 97% at Malin Head. Global radiation was about 125% of average at Dublin Airport and Valentia Observatory and over 100% at Birr and Kilkenny.

Strong Winds with Gale Gusts became general on 9th/10th.

Summary Very dry, warm and sunny. Drought conditions were severe in regions away from the northwest, and were particularly severe in the south and southeast.

The data contained in this Bulletin are Provisional. Some of the material in Table 1 will be published in its final form later in the Monthly Weather Report; final values of Solar Radiation at stations in Table 2 will be published in the Annual Summary of Solar Radiation.

Notes on the tables in January issue

special topic

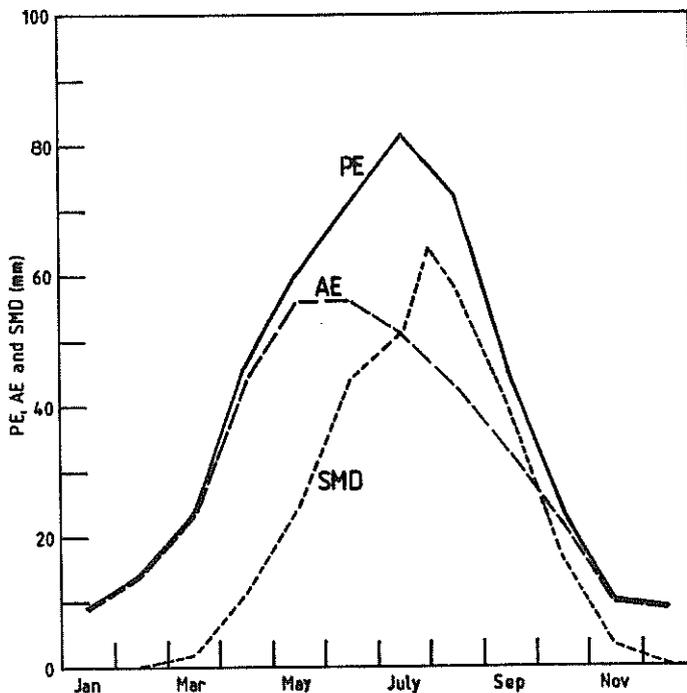

Evaporation and Soil Moisture (Continued from June)

Soil moisture deficits reach their maximum in July and August and may be sufficiently great to restrict growth. Eastern and midland regions are normally affected most where there are relatively low rainfall amounts and greater sunshine values as compared to western and northern areas, where least restriction to growth occurs. The moisture deficits decline in early autumn and a return to field capacity occurs later in the season. By early winter, the ground may become saturated or even water-logged bringing the sowing of winter cereals and other field work to a standstill.

In a particular year, however, conditions will differ markedly from the average year. The spring may be cold and wet at certain critical times. The summer may be broken and damp or excessively dry on other occasions, causing stress to crops. Small soil moisture deficits are beneficial and many growing crops can adapt to fairly large deficits without any disadvantage. Indeed, some root crops adapt to moderate deficits to good effect, being induced to penetrate deeper and extend their roots in search of water. Grass is little affected by a deficit of 50 mm, mature cereals will overcome a deficit of 75 mm without any adverse affect whereas such a high value would cause severe stress to grass.

An instrument, which gives a measure of potential evapotranspiration from a grass surface, is the Thorntwaite lysimeter. The purpose of the instrument is the measurement of the amount of water disposed of by a growing crop (grass in our case) by the process of evaporation and transpiration. A necessary condition for these measurements is that the soil in which the plants are growing has an adequate supply of water.

This lysimeter consists of a sunken tank filled with soil and having a short grass sward, and provided with a run-off tube in the bottom. Once per day a known quantity of water is applied to the soil, enough to ensure some run-off. The amount of water disposed by evaporation is the difference between the amount supplied and the run-off. In practice four such tanks are maintained and an average is obtained over ten-day periods.

There are six such instruments in operation throughout the country representing each of the regions. From the values of potential evapotranspiration, actual evapotranspiration and moisture surpluses or cumulative soil moisture deficits, as appropriate, can be calculated from theoretical considerations.

The annual course of monthly values of potential evapotranspiration (PE), actual evapotranspiration (AE) and end of month soil moisture deficits (SMD) at Oak Park, Co. Carlow, averaged of the ten-years, 1971 to 1980, are shown in the figure over.
