

METEOROLOGICAL SERVICE

SEPTEMBER 1986

AGROMETEOROLOGICAL BULLETIN

The Weather of September

A west to northwest airflow prevailed on 1st/2nd and associated frontal troughs gave spells of rain. Improved conditions set in on the 3rd as high pressure from the North Atlantic developed over Ireland. When the high pressure cell drifted in over Europe, weak troughs affected coastal areas of the south and north on the 5th/6th, and there was a partial influx of warm air in southwestern areas.

A zone of rising pressure over northern regions of the North Atlantic extended down over Ireland on 6th/7th. The weather became settled; subsequent conditions were bright, dry but rather cold. In particular night-time minimum temperatures were several degrees below normal. A slack north to northeasterly airflow prevailed.

As high pressure receded westwards, showers developed over the country in the northerly airflow on 13th/14th. The Atlantic high re-intensified and extended further southward, so that there was a recovery of pressure from the west and southwest on the 15th. This high pressure became the dominant feature for weather over Ireland for the remainder of the month. Occasional troughs and freshening southwest winds affected northwestern areas on 19th/20th. As the high declined into Europe, freshening southwest winds became more extensive over Ireland on 27th. The ensuing airmass was very mild and humid with extensive fog, particularly in coastal areas. However, daytime conditions were very warm and sunny and the influence of the high pressure, which became centred over Europe, remained effective over the country through the end of the month.

Precipitation:

In sharp contrast to the summer months, which proved to be extremely wet and cold, September was exceptionally dry. For most areas it was the driest September on record and in some parts it was the driest month ever recorded. Precipitation amounts varied from as little as less than 1% of normal at Lullymore to a maximum of 29% at Malin Head.

Temperature:

Both the daytime maxima and in particular the night-time minima were well below normal especially during much of the first three weeks of the month. For the month as a whole mean air temperature varied from 1.1°C below normal at Malin Head and Kilkenny to 2.2°C below at Belmullet. Up to 1°C of air frost occurred at some places in the southmidlands on 16th or 19th. Ground frost was extensive on 7th, 9th, and 12th to 19th. Soil temperature was also well below average.

Sunshine and Radiation:

Again in sharp contrast to previous months, sunshine was well above normal. Total sunshine hours varied from 157% of normal at Clones to 112% at Rosslare. Global radiation was about 15% above average.

Wind:

Winds were mostly light to moderate except in the north on 19th/20th and in the west and north on 27th/28th and 30th when there were gale gusts.

Summary:

Exceptionally dry, very sunny but rather cold.

The data contained in this Bulletin are provisional. Some of the material in Table 1 will be published in its final form in the Monthly Weather Report; final values of Global Radiation at stations in Table 2 will be published in the annual Solar Radiation Observations.

special topic

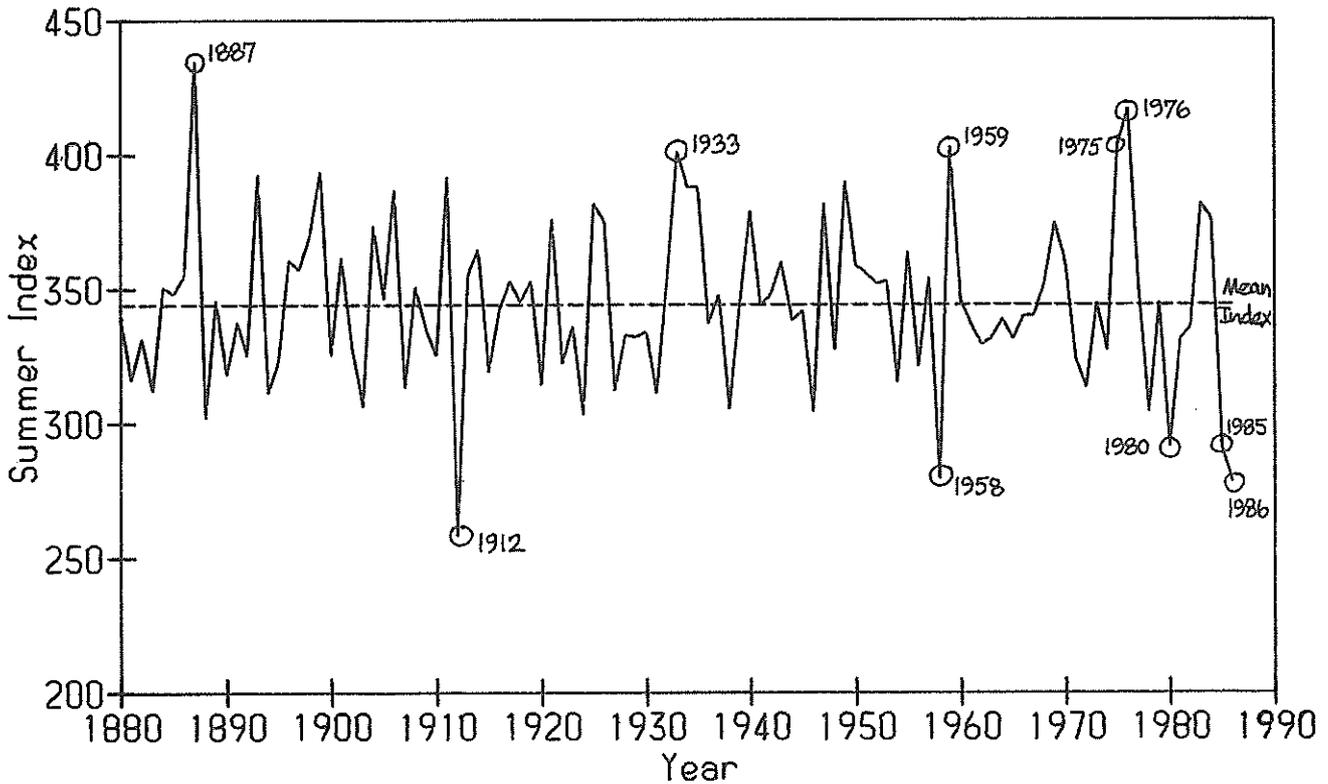

SUMMER INDEX

The weather of a month, season or year is frequently evaluated by comparing certain elements, e.g. precipitation amounts, mean air temperature, sunshine hours, to the normal values for the period. Other criteria often used include accumulated temperature, number of days with maximum temperature exceeding a certain value (e.g. 21°C) and the Poulter Index. The latter is used to express the overall quality of a summer (June to August inclusive) by means of a single figure derived from the sum of weighted values of mean air temperature, total sunshine and total rainfall. High values of the first two elements and low values of rainfall result in a high Index criteria. In a most general way therefore large values of the Summer Index reflect the brighter and drier summer seasons and low values correspond to the cooler, duller and wet seasons. It has been found that the outcome of operations which are very much weather dependent and extend throughout the (summer) season show close association with year-to-year variations in the Index. Milled peat production, for example, has been shown to correlate highly with the Poulter Index for the period May to September inclusive,

The figure below shows the values of the Poulter Summer Index at the Phoenix Park by year since 1880. Considerable year-to-year fluctuation is evident including a number of extreme values (high and low values of the Index). Individual summer seasons can be identified and sequences of seasons. It needs to be stressed, however, that while the number of similar type extreme seasons occurring in sequence are rare, it is not possible to predict upcoming summers by extrapolation of the Index to future years.
