

AGROMETEOROLOGICAL BULLETIN.

The Weather of May 1990

Summary

1st-4th : Settled conditions in easterly or light winds.
5th-9th : Cool west to northwest airflow and troughs . 10th-16th : mild southerly (SE-SW) airflow/rainbelts
17th-22nd : Light east-northeasterly, dry; some mist and fog, and thunder in south.
23rd-27th : High pressure and settled conditions. 28th-31st : Active rainbelts, variable wind

Meteorological Situation

High pressure tended to recur in the Atlantic-European seaboard from the Azores to the Norwegian Sea. Warm, sunny conditions during opening four days gave way to the increasing influence of troughs. A low moved down from the Icelandic region via Scotland and Britain on 5th/6th followed by an associated trough. Subsequent conditions to 9th included northwesterly winds and showers occasionally merging to rain in the northeast.. As the Azores high declined, an Atlantic low pressure system and southwesterly winds steered troughs to Ireland on 10th/11th. Later a more general decline of pressure enabled a series of troughs to affect the country from 13th to 16th.

Subsequently a high built down from northern latitudes and Atlantic troughs moved towards Biscay. Dry weather developed over the country in an east to northeast airflow; some mist and fog also occurred as well as a few thundery outbreaks of rain in southern areas. The high extended across Ireland to Azores on 21st but a decline from the north allowed a trough and northwest winds to affect the country on 22nd. The Atlantic high recovered again giving settled conditions to 27th. It finally receded into mainland Europe, and rainbelts became more active over the country, especially on 28th/29th and 31st.

Precipitation

Precipitation was mostly below to well below normal. It varied from 29% of normal at Glenamoy to 91% at Kinsealy (but 110% at Ardee, Co Louth). Driest spells were 1st-6th, 11th-13th (1st-13th in south) and 17th-27th. Wettest days were 7th-9th, 14th-16th and 28th-31st. Soil moisture deficits at the end of the month varied from about 50 to 65 mm but was only 22 mm at Cahirciveen.

Wind

Strong winds with gale gusts were infrequent. Some gale gusts occurred on 14th to 16th and 31st.

Temperature

Mean air temperature was well above normal everywhere. It varied from 2.4°C above normal at Shannon Airport to 1.1°C above at Malin Head. Highest temperatures occurred in the opening four days when 25°C was exceeded a number of times. Lowest values were reached in the periods 7th to 11th and 24th to 26th.

Soil temperature was generally 2°C to 3°C above average, and over 5°C above in the first 5-day spell.

Sunshine and Radiation

Bright sunshine hours were above normal except at Belmullet. Totals varied from 123% of normal at Malin Head to 101% at Clones, and 93% at Belmullet. Global radiation was 113% of average at Dublin Airport and 115% at Cahirciveen.

May 1990

IMPLICATIONS OF CLIMATE CHANGE FOR AGRICULTURE

(continued from the April Bulletin)

Water Balance

A 15 per cent increase in potential evapotranspiration (PE) in winter and a 10 per cent increase in summer (assuming a 5 per cent change in PE for every 1°C) is possible (see Table 1, April Bulletin). Changes in precipitation are less certain—an increase of about 15 per cent in winter and 5 per cent in summer is indicated by the models—but rain spells may be confined to more intense storms rather than prolonged light falls.

Water Table

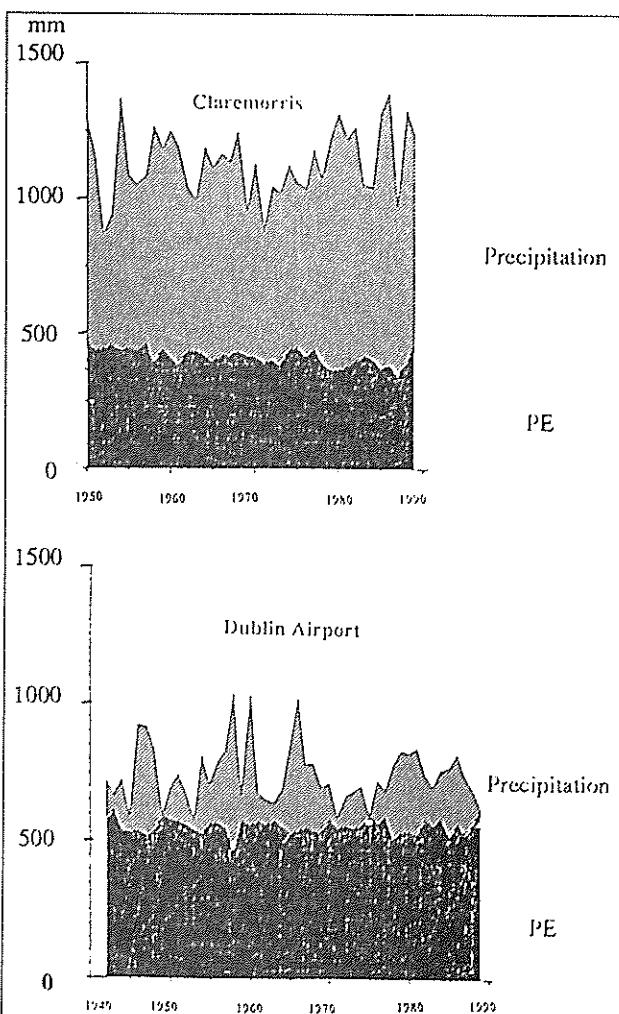

Because of increased rainfall in winter and spring the timing of various spring farm operations such as ploughing, fertilizing, beginning of grazing, etc, would be affected. Turn-out date would also be delayed due to slow drying of the soil and the season may end earlier in the autumn. Difficulties would attend utilization (grazing/silage making) of the increased herbage produced early in the season and again at late harvesting. A higher water table level would also lead to much less stock being carried on wet soils compared with dry grassland. Conditions in the wetter areas would be affected most. These considerations indicate new difficulties for the farmer at the extremities of the growing season (in a changed but wetter spring and autumn).

Summer Drought

Additional difficulties are likely in summer. An increase of 5 per cent in summer rainfall would not compensate for an expected 10 per cent increase in PE (as summer PE is normally greater than summer rainfall). Increased moisture shortfall would thus lead to large soil moisture deficits and greater risk of more frequent drought. Irrigation of crops, particularly in the south and east may become a more common practice in this country.

Radiation

Models are less in agreement with respect to changes in radiation—some predict increased cloudiness but it may be of the thin type that is easily dissipated. Given the rise in temperature and more concentrated rainfall events in summer, radiation may well be enhanced by at least 5 per cent. As a result of both the increase in temperature and radiation, growth rates will be accelerated. Earlier times of harvesting, e.g. sugar beet which is now harvested in October and November, would benefit quality and reduce spoilage due to better condition of soil and trafficability.

The year-to-year changes in the balance between annual precipitation and PE (Penman) is shown above. The excess of precipitation over PE is normally double at Claremorris whereas both are of the same order of magnitude at Dublin Airport. A small climate change to less summer rainfall and greater PE would easily lead to severe moisture deficits during the peak growing season, especially in the east and south.

(concluded in next issue)
